Abstract

Introduction: Black glutinous rice (*Oriza sativa var glutinosa*) and green tea (*Camelia sinensis*) are plants that are useful for moisturizing the skin. The purpose of this study was to obtain the best formulation of peel-off gel mask preparations from black glutinous rice and green tea extract.

Method: The gel mask formulation was made on the basis of variations in the concentration of Hydroxy Propyl Methyl Cellulose (HPMC) of F1 (2,5%), F2 (3%) and F3 (3,5%) with evaluation including organoleptic tests, pH, viscosity, homogeneity, dispersity test, and drying time at temperatures of 4°C, 25°C, 40°C for 28 days.

Results: The evaluation results of the three formulations met the requirements for a good peel-off gel mask. pH results are between 4.6-5.5 which is still in the standard range of 4.5-6.0. The results of the viscosity test are 6.500-12.166.7 cps which are in the range of 6.000-24.000 cps, the dispersion area meets the requirements of 5-7 cm, the result of the drying time is 15-22 minutes which are in the range of 15-30 minutes.

Conclusion: The conclusion of this study was that F1, F2, and F3 met all the requirements for peel off gel masks by storing at temperatures of 4°C, 25°C, 40°C for 28 days.

Keywords: peel-off mask, black glutinous rice extract, green tea extract, HPMC, stability test.

INTRODUCTION

Currently, the use of natural ingredients that are safer for the skin has been developed as a source of antioxidants in cosmetic preparations. Antioxidants are compounds that are useful for neutralizing the increase in free radicals, protecting cells from the resulting toxic effects and can also contribute to the prevention of diseases. Antioxidants are found in many plants. One of them is black glutinous rice (*Oryza sativa var glutinosa*). Black glutinous rice is one type of rice that contains secondary metabolites such as alkaloids, flavonoids, tannins and steroids (Iryani et al., 2017). Black glutinous rice contains anthocyanin pigments. Anthocyanins are pigments from the flavonoid group that are soluble in water, have a red to blue color and are widely distributed in plants. (Rantika et al., 2019). In addition to black glutinous rice, another natural active ingredient that contains antioxidants is green tea. The composition of tea leaves is known to be very complex. More than 400 chemical components have been identified in tea leaves. The amount of this chemical component varies depending on the soil, climate, and the age of the tea leaves when picked. Catechins (polyphenols) are powerful antioxidants, stronger than vitamins E, C and -carotene (Habiburrohman Denny and Sukohar Asep, 2018). The main content of catechins (polyphenols) in green tea, especially epicatechin (EC), epigallocatechin (EGC), epicatechin galatate (ECG) and EGC gallate have proven to be used as antioxidants (Fajar et al., 2018). Antioxidants can produce a better effect when formulated in topical dosage forms on the face because the active substances can interact longer on the face. One of the topical dosage forms that has been widely developed is the peel-off mask. Peel-off gel mask is an alternative preparation that can increase the comfort of use and is expected to increase the antioxidant activity of black glutinous rice and green tea with the effect of using a peel-off gel mask base, namely Polyvinyl Alcohol (PVA) (Mufluhunna et al., 2019). PVA is a very important ingredient in the formulation of peel-off mask preparations, because PVA plays a role in providing a peel-off effect because it has adhesive properties so that it can form a film that is easy to peel off after drying. Based on the results of research that has been carried out, the concentration of PVA which is used as a film-forming layer for a peel-off gel facial mask can be used with PVA with a concentration range of 10-16% having the most

optimal pharmaceutical stability (Sulastri and Chaerunisa, 2018).

From several studies that have been carried out, I want to make a combination formulation of black glutinous rice and green tea which is currently still rarely developed in the form of a peel-off mask. Research on the preparation of a peel-off gel mask from green tea leaf extract (*Camellia sinensis*) and rice Black sticky rice (*Oryza Sativa* var *Glutinosa*) with various HPMC base concentrations of 2.5%, 3%, 3.5% was developed into cosmetic preparations used topically by the public.

METHOD

Peel off mask optimization

Tests of several concentrations of additives used for create an optimum peel off mask formula. Optimization is expected to produce formula with maintained stability based on several tests. As for the formula master that have been optimized are:

Table 1. Peel-Off Mask Preparation Formula (Nurwaini and Sari, 2019).

Bahan (%)	Formula			Fungsi
	I	II	III	
Black Glutinous Rice Extract	4,6	4,6	4,6	<i>Skin lightening</i>
Green Tea Extract	0,16	0,16	0,16	<i>Skin lightening</i>
Polyvinil alcohol	10	10	10	<i>Gelling agent</i>
Propylenglikol	12	12	12	<i>Stabilizer</i>
HPMC	2,5	3	3,5	<i>Gelling agent</i>
Metil Paraben	0,3	0,3	0,3	Pengawet
Aqua Destillata ad	100	100	100	Pelarut

Preparation of Peel-off Masks

The materials were weighed, HPMC was developed by adding aquadest at a temperature of 70-80°C then stirred until it was clear and homogeneous (mixture I). Polyvinyl alcohol was added with distilled water at room temperature, then heated on a water bath at 80°C until it swelled completely, then cooled. Then homogenize using a homogenizer (mixture II). Then enter Mixture I into Mixture II) little by little, homogenize using a homogenizer until a base becomes a gel (mixture III). Propylene glycol and methyl paraben were mixed until homogeneous (mixture IV). Mix III is put into mixture IV and add black glutinous rice extract and green tea extract. All materials were homogenized using a homogenizer at the optimum speed and time. The preparation was left for 48 hours to remove the foam. An evaluation of the formulation was carried out (Kindangen et al., 2018).

Stability Testing of Physical Properties of Peel-Off Gel Mask Preparations

1. Organoleptic observations

Organoleptic testing was carried out by observing changes in shape, color, and odor of the gel mask preparation. Tests were carried out at storage temperatures of 4°C, 25°C, 40°C on days 0, 7, 14, 21, 28 (Mufluhunna et al., 2019).

2. pH testing

Measurement of the pH of the preparation was carried out using a pH meter. The pH of the mask preparation must be in accordance with the pH of the skin, which is 4.5–6.5. A number of peel-off mask gels are inserted into the pH meter. Tests were carried out at storage temperatures of 4°C, 25°C, 40°C on days 0, 7, 14, 21, 28 (Wulansari et al., 2020).

4. Viscosity Test

Viscosity determination was carried out using a Brookfield type LV viscometer. A total of 250 ml of gel was put into a 250 ml beaker glass then put the spindle immersed in the preparation. Then the spindle speed is set successively 0,5, 2, 5, 10, 20 rpm then reversed 20, 10, 5, 2, 0,5 the scale is read when the moving red needle has stabilized. Tests were carried out at storage temperatures of 40C,

250C, 400C on days 0, 7, 14, 21, 28. The viscosity value of a good peel-off gel mask preparation is 3000-50,000 cps (Rantika et al., 2019).

5. Homogeneity Test

The homogeneity test is carried out by placing the preparation on a slide, then seeing whether there are coarse particles or inhomogeneities. Tests were carried out at storage temperatures of 4°C, 25°C, 40°C on days 0, 7, 14, 21, 28 (Santoso et al., 2020).

6. Drying Preparation Time Test

1 gram of peel-off mask gel is applied to the skin of the arm with a length of 7 cm and a width of 7 cm. Then the speed of drying the gel was calculated to form a film layer of the peel-off mask gel using a stopwatch. Tests were carried out at storage temperatures of 4°C, 25°C, 40°C on days 0, 7, 14, 21, 28. A good drying time for peel-off gel mask preparations is 15-30 minutes (Zubaydah and Fandinata, 2020).

RESULTS

Stability Test Results of Physical Properties Peel-Off gel mask

Stability test of the physical properties of peel-off masks was carried out at temperatures of 40C, 250C, 400C on days 0, 7, 14, 21 and 28 which included organoleptic examination, pH, viscosity, homogeneity, spreadability and drying time.

DISCUSSION

This study aims to determine the physical stability of peel-off gel masks from extracts of black glutinous rice (*Oryza sativa* var. *glutinosa*) and green tea (*Camellia sinensis*) with various HPMC concentrations of 2.5%, 3% and 3.5% stored at 40C, 250C and 400C for 28 days. This variation was carried out to optimize the concentration of an effective base to meet the criteria for the physical properties of pharmaceutical peel off masks and to survive in shelf life through stability testing.

The tests based on physical parameters include organoleptic examination, homogeneity, viscosity measurement, pH measurement, dispersion and drying time. The organoleptic test aims to observe the shape, color and odor of the peel-off mask preparation. Based on the results of the organoleptic evaluation of the peel-off mask preparations of black glutinous rice extract and green tea after being stored for 28 days at 40C, 250C and 400C, it showed that the three formulas were brown in color resulting from the addition of black glutinous rice extract (*Oryza sativa* var. *glutinosa*).) and green tea (*Camellia sinensis* L.) then for the color, odor and texture of each formula did not change from the beginning of manufacture to the storage limit and had a characteristic green tea odor that was consistent from the beginning of manufacture until the storage time limit. The resulting product is organoleptically stable (Muflihunna *et al.*, 2019). It is important to measure pH to ensure that the pH of the preparation is in accordance with the pH of the skin, so that irritation can be avoided. Peel-off masks are preparations that are applied to facial skin so that the pH value of the preparation must match the pH of the facial skin, which is 4.5-6.5. Because if the pH value of a preparation is too acidic <4.5 it will cause skin irritation, whereas if the pH value of a preparation is >6.5 or too alkaline it can cause scaly skin (Kulkarni *et al.*, 2019). The results of the pH test showed that all formulas had a pH in the range of 4.5-6.5 for topical preparations. pH after being stored for 28 days did not change significantly. Stable pH indicates that the components in the preparation are still in the pH range category and are not affected by temperature so that the preparation remains stable during storage. So that the results of pH measurements for formulas based on HPMC were concluded to be stable and safe to use even though they decreased after forced conditions, but the decrease in pH indicated was very small and still acceptable because it still met the pH range of preparations for skin.

The viscosity test on the peel-off gel mask preparation aims to determine the effect of the concentration of the active substance on the viscosity of the preparation. The viscosity of the preparation needs to be guaranteed to produce an optimal gel. Gels with too low a viscosity cause contact time with the skin not long enough so that the activity of the active ingredients is not optimal, a large viscosity increases

retention time at the application site, but also reduces dispersion (Santoso et al., 2020). From the examination of viscosity using a Brookfield Viscometer type LV with spindle 4 at a speed of 12 rpm. In general, the viscosity of the three preparations is still in the standard range, which is between 6000 – 24000 cps (Hairiyah and Nuryati, 2016). The increase in gel viscosity is influenced by an increase in the concentration of the gelling agent. Increasing the concentration of PVA and HPMC can increase the number of polymer fibers so that more liquid is retained and bound by the gelling agent so that the viscosity of the preparation increases. The increasing concentration of HPMC can increase the viscosity of the peel-off gel mask preparation. (Zubaydah and Fandinata, 2020). While this decrease occurs because the longer the storage time, the longer the preparation is affected by the environment, for example by air. Then the use of less impermeable packaging can also cause the preparation to absorb water from the outside, thereby increasing the volume of water in the preparation (Suryani et al., 2019).

Homogeneity testing aims to observe the presence or absence of coarse particles. Homogeneity is the arrangement of the dispersion phase in the dispersion medium evenly. This is related to the mechanism of action of antioxidants, which function as antioxidants are extracts of black glutinous rice (*Oryza sativa* var. *glutinosa*) and green tea (*Camellia sinensis* L.). Therefore, extracts of black glutinous rice (*Oryza sativa* var. *glutinosa*) and green tea (*Camellia sinensis* L.) must be homogeneously distributed on the mask base so that their effectiveness as antioxidants can be uniform. In terms of homogeneity, at room temperature from the beginning of manufacture until the 28th day the three formulas were homogeneous and did not show any coarse grains when the preparation was smeared on transparent glass. This shows that the composition of the ingredients in the three formulations is dissolved or evenly dispersed (Ningsih et al., 2016). Likewise, at a cold temperature of 4°C and a hot temperature of 40°C, the three formulas did not show the presence of coarse grains.

The spreadability test is intended to determine the ability to spread the gel when applied to the skin. Dispersion is an important characteristic in formulations because it affects the transfer of the active ingredient to the target area in the right dose, ease of use, the pressure required to get out of the package and acceptance by consumers (Santoso et al., 2020). From the measurement results, these results indicate that the dispersion area meets the requirements of 5-7 cm (Setia, 2018). A good peel-off gel mask takes less time to spread and will have a high spreadability value. The greater the spreadability, the better the spread of the mask on the skin area to which the mask is applied. The decrease in dispersion occurs through an increase in the size of the molecular unit because it has absorbed the solvent so that the liquid is retained and increases the resistance to flow and spread (Kindangen et al., 2018).

The drying time test is expected to get a good film formulation to be applied, this is also related to user comfort when using it. If the peel-off gel mask preparation dries quickly, it can be said that the preparation is very good to use because in application it does not take a long time to take effect, whereas if the preparation dries for a long time then the preparation also takes a long time to take effect so that sometimes it causes an unpleasant taste. comfortable to use. The expected drying time of the resulting peel-off gel mask is between 15-30 minutes (Leslie and Gunawan, 2019). The difference in drying speed in each formula is influenced by the amount of water concentration contained in the formula so that the drying speed will be longer. The increase in drying time during the 28-day storage period both at room temperature, hot temperatures and cold temperatures can occur because the longer the storage time, the longer the preparation is affected by the environment, for example air (Rantika et al., 2019).

CONCLUSION

From the research that has been done, it can be concluded:

1. Black glutinous rice extract and green tea can be formulated as a peel-off gel mask preparation with HPMC bases of 2.5%, 3%, and 3.5%
2. The formulation of the peel-off gel mask was concluded to be pharmaceutically stable based on the tests that have been carried out, namely:
 - a. In the organoleptic test F1, F2, F3 each formula during storage for 28 days at 3 temperatures, namely 4°C, 25°C, 40°C, there was no change in color, smell and texture, this shows that each formula meets the requirements and the homogeneity test shows the three formulas are homogeneous and there are no coarse grains.
 - b. In the pH test F1, F2, F3 each formula during storage for 28 days at 3 temperatures, namely 4°C,

- 25°C, 40°C F1 = 4,9-5,2, F2 = 5,3-5,5, at F3 = 4,6-4,8 indicates a result that meets the requirements of the pH range that can be accepted by the skin, namely pH 4.5 - 6.5.
- c. In the F1, F2, F3 viscosity test each formula was stored for 28 days at 3 temperatures, namely 4°C, 25°C, 40°C. In F1 the preparation has a viscosity of 10000 cps, for F2 it is 10333 cps, while the viscosity of the F3 preparation is 12166,7 cps. In general, the viscosity of the three preparations is still in the standard range, which is between 6000 – 24000 cps
 - d. In the F1, F2, F3 dispersion test of each formula during storage for 28 days at 3 temperatures, namely 4°C, 25°C, 40°C at F1 which was 6,3, F2 was 6,1 and F3 obtained 6,1 spreadability. the three formulas still enter the standard range of 5-7 cm
 - e. In the long drying time test F1, F2, F3 each formula was stored for 28 days at 3 temperatures, namely 4°C, 25°C, 40°C. the length of time for F1 to dry ranges from 15-18 minutes, then F2 16-21 minutes and F3 16-20 this is still in the range of 15-30 minutes.
3. Of the three formulas in Formula 1 with HPMC concentration of 2.5% gave the best results seen from the results of the dispersion test where the dispersion area in formula 1 was the highest than the other formulas and the drying time test in formula 1 had an average The average drying time is the fastest among other formulas so that it is the most effective preparation in its use.
